➤ **Criteria for use**

For the diagnosis and management of pregnant women with severe hypertension, pre-eclampsia and eclampsia.

➤ **Background/ introduction**

Hypertensive disorders of pregnancy remain a leading cause of direct maternal deaths. In the last confidential enquiry¹, there were 18 deaths, at a rate of 0.85 deaths per 100,000 maternities. The most common aetiology of hypertensive deaths was intracranial haemorrhage secondary to uncontrolled systolic hypertension; the failure of effective anti-hypertensive therapy was the most common source of sub-standard care. However, over the last 20 years there were also deaths from pulmonary oedema secondary to fluid overload; this has been decreasing due to greater emphasis on fluid balance.

Specific learning points from the CEMACH report are as follows:

1. Systolic hypertension of 160 mmHg must be treated.
2. Syntocinon should be given for the management of the third stage if the mother is hypertensive or if her blood pressure (BP) has not been checked prior to its administration.
3. The anaesthetist should be given as much time as possible to try and prevent the pressor effects of intubation in the pre-eclamptic woman, even if there are pressing fetal reasons for urgent caesarean section under general anaesthesia.
4. Severe life-threatening pre-eclampsia can occur at any gestation: preterm, term, post-term or postpartum.

Diagnosis of pre-eclampsia:

- Persistently elevated BP of 140/90 in a patient without pre-existing hypertension
- New proteinuria of 1+ or more on dipstick; or urine protein: creatinine ratio (uPCR) greater than 30mg/nmol; or 0.3g protein/24 hours in a 24 hour urine collection.

Severe pre-eclampsia

In addition severe pre-eclampsia may present with one or more of the following:

- Symptoms and signs:
 - Severe hypertension with a systolic BP ≥ 160 on two occasions or diastolic BP ≥ 110 on two occasions
 - Severe persistent headache
 - Visual disturbance
 - Nausea and Vomiting
 - Epigastric or right upper quadrant pain and tenderness
 - Hyperreflexia with more than 2 beats of clonus
 - Papilloedema
- Abnormal Laboratory investigations:
 - Significant proteinuria (at least 1g/24 hours or uPCR of greater than 100 mg/nmol)
 - Falling platelet count $< 100 \times 10^9/L$
 - Raised urate level
 - Raised AST or ALT
 - Abnormal renal function
 - DIC (unlikely if platelets $>100 \times 10^9/L^1$)

- **Haemolysis, Elevated Liver enzymes and Low Platelets (HELLP) syndrome**
 - A severe presentation of pre-eclampsia
 - Diagnosed by confirming haemolysis by raised lactate dehydrogenase (LDH) or a blood film to look for fragmented red cells; an AST above 75 iu/L; and a platelet count below $100 \times 10^9/L^1$.

Eclampsia

Eclampsia is defined as the occurrence of one or more convulsions superimposed on pre-eclampsia¹

Inclusion criteria for severe pre-eclampsia/ eclampsia protocol

1. Blood pressure greater than or equal to 160/110
2. Eclampsia
3. Deteriorating condition i.e. the presence of symptoms, rapidly deteriorating kidney or liver function or platelets

If these criteria are met, the patient should be managed according to the protocol below.

➤ **Clinical management**

The aims of management are:

- Prompt control of blood pressure
- Meticulous fluid balance to avoid fluid overload
- Prophylaxis or treatment of eclamptic seizures
- Prompt delivery of fetus by vaginal or abdominal route
- Regular review of all parameters
- Monitoring for serious complications of severe pre-eclampsia

See: Algorithm 1: Overall management plan

Algorithm 2: Fluid management

Algorithm 3: Blood pressure management

Pre eclampsia, Eclampsia and Severe Hypertension. C.Biswas.Cons Obstetrician. May 2014.V4

Algorithm 4: Eclampsia management

Algorithm 5: Magnesium Sulphate management

General measures (see Algorithm 1):

1. Once the decision has been made to commence the woman on the severe pre-eclampsia protocol: print out checklist (appendix C), file into notes and start it.
2. Inform Consultant Obstetrician; Labour Ward (LW) anaesthetist who should inform the on-call consultant anaesthetist; labour ward co-ordinator; and neonatal team if patient is antenatal.
3. The consultant haematologist on-call and intensive care unit (ICU) team may also need to be informed depending on the situation.
4. Admit to Labour Ward (LW).
5. IV access with at least one large bore cannula.
6. Give ranitidine 150 mg (orally) and repeat 12 hourly.
7. Monitor the fetus with continuous CTG until delivery.
8. Monitor all mother's observations on Modified Early Obstetric Warning (MEOWs) chart.

Planning for delivery

1. Corticosteroid for fetal lung maturation: Give betamethasone or dexamethasone 12mg IM 2 doses 12 hours apart⁴ if delivery is likely in a woman between 24 and 34 weeks gestation, and consider between 34 and 36 weeks gestation.
2. Decision for delivery and mode of delivery: This should be made in conjunction with the consultant obstetrician, and consultant neonatologist if appropriate.
3. If allowed to labour, the fetus should be assessed with continuous electronic fetal heart rate pattern monitoring.

4. 2nd stage: Operative birth should be advised for those women in second stage of labour whose severe hypertension has not been controlled by initial treatment. This is not necessary for those with blood pressure treated to the target range⁴.
5. 3rd stage: manage this with Syntocinon® 10 iu IM or slow IV administration.
6. The prophylaxis or treatment of postpartum haemorrhage with 40 units oxytocin (Syntocinon®)³ should be administered in the following way⁶:

Oxytocin (Syntocinon®) 40IU in 100 mls normal saline at 26mls/ hour; via IV infusion pump.

Fluid Management (see algorithm 2):

Special care should be taken in the fluid management of the woman with severe pre-eclampsia who has also undergone obstetric haemorrhage.

1. A urinary catheter should be inserted and urine output measured hourly.
2. Total intravenous fluid input should be limited to 1ml/kg/hr- approximately 80mls/hour. This is **inclusive** of oxytocin (Syntocinon®) and magnesium sulphate (MgSO₄) infusions; and oral intake if eating/drinking whilst on the severe pre-eclampsia / eclampsia protocol.
3. Fluid loading in pre-eclampsia should **never** be done prophylactically or routinely, as there is no evidence of the benefit of fluid expansion^{2,3}. Consider a fluid load of 500 mls crystalloid prior to administration of the first dose of hydralazine, but not of other anti-hypertensive drugs⁴.

4. Postpartum oxytocin (Syntocinon®) –10 units /hr should be given to women with fluid restriction on the severe PET protocol in the formula given above.
5. Urine Output:
 - a. Intrapartum: Oliguria should not precipitate any intervention except to ensure progress to delivery³.
 - b. Postpartum: Continue to restrict fluids until a natural diuresis, which may occur at 36-48 hours postpartum
 - c. See algorithm 2.

Magnesium Sulphate for the treatment and prevention of eclampsia (Algorithms 4 and 5)

Inclusion criteria a) OR b)

- a) Eclamptic fit
- b) Consider giving intravenous magnesium sulphate to women with severe pre-eclampsia if they have BP >140/90 AND proteinuria > 2+ AND at least one of the following:
 - a. Persistent severe headache
 - b. Epigastric pain, vomiting or liver tenderness
 - c. Visual disturbance
 - d. Hyperreflexia with > 2 beats clonus
 - e. Platelet count < 100 x 10⁹
 - f. ALT > 70 iu/L
 - g. HELLP syndrome

Always inform the Obstetric and Anaesthetic consultants on call if a patient is commenced on MgSO₄.

➤ **Anaesthetic considerations**

Please see Whittington Health Guideline:

'Obstetric Anaesthesia'

Serious complications secondary to severe pre-eclampsia

The following rare but serious complications should be considered if the woman presents with the relevant symptoms and signs¹:

Neurological: Intracranial haemorrhage

 Subarachnoid Haemorrhage

 Ischaemic Stroke

 Cortical Blindness

 Cavernous sinus thrombosis

 Cerebral oedema

Pulmonary: Pulmonary oedema

 Adult Respiratory Distress Syndrome (ARDS)

Hepatic Liver rupture

 Liver failure/necrosis

Renal Renal failure

➤ Postpartum Management

Note: 44% of eclamptic fits occur during the postnatal period⁵

1. The patient should remain on the Labour Ward for at least 24 hours after delivery. The blood pressure and fluid balance should be recorded on the Labour Ward MEOWS chart.
2. When the woman is transferred to the postnatal ward, the blood pressure should be measured four-hourly on the postnatal MEOWS chart until she is discharged. She should be asked about severe headache and epigastric pain whenever the blood pressure is measured⁴. A fluid balance chart should be kept for at least 72 hours or until the serum creatinine levels are in the normal range.
3. Blood parameters (platelets, serum transaminases and serum creatinine) should be measured 48-72 hours after delivery, and if normal, they should not be repeated again. However they should continue to be repeated as clinically indicated if they are improving but still within the abnormal range.
4. The blood pressure should be kept below 150/100. If the woman was treated prior to delivery she should continue with her antenatal medication, except methyldopa which should be changed to another medication within 2 days of delivery. If the woman was not treated prior to delivery, anti-hypertensive treatment should be started for the first time if the blood pressure exceeds 150/100.

The following antihypertensive medications are suitable for the breast-feeding postnatal woman⁴: Healthcare professionals may prescribe these medicines during breastfeeding if they consider that this treatment is essential for the lactating mother. Careful follow-up of the infant for possible signs of hypotension is recommended.⁸

Labetolol

Nifedipine

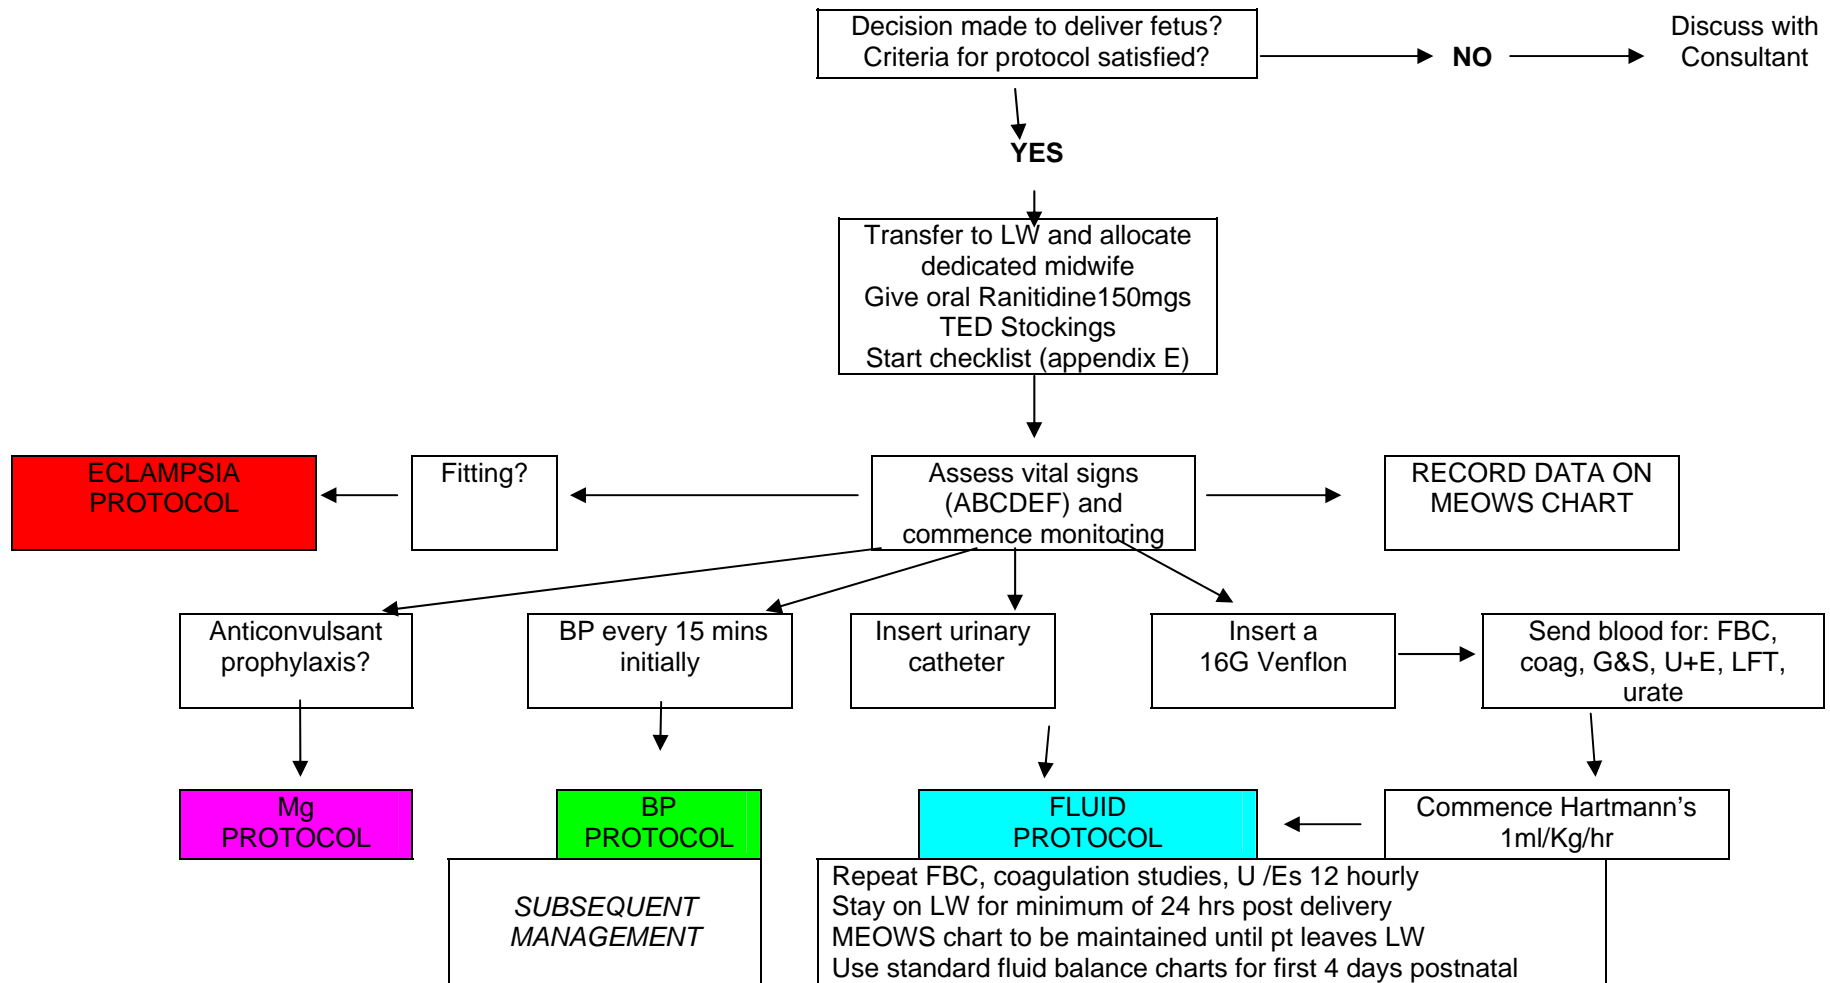

Enalapril

Atenolol

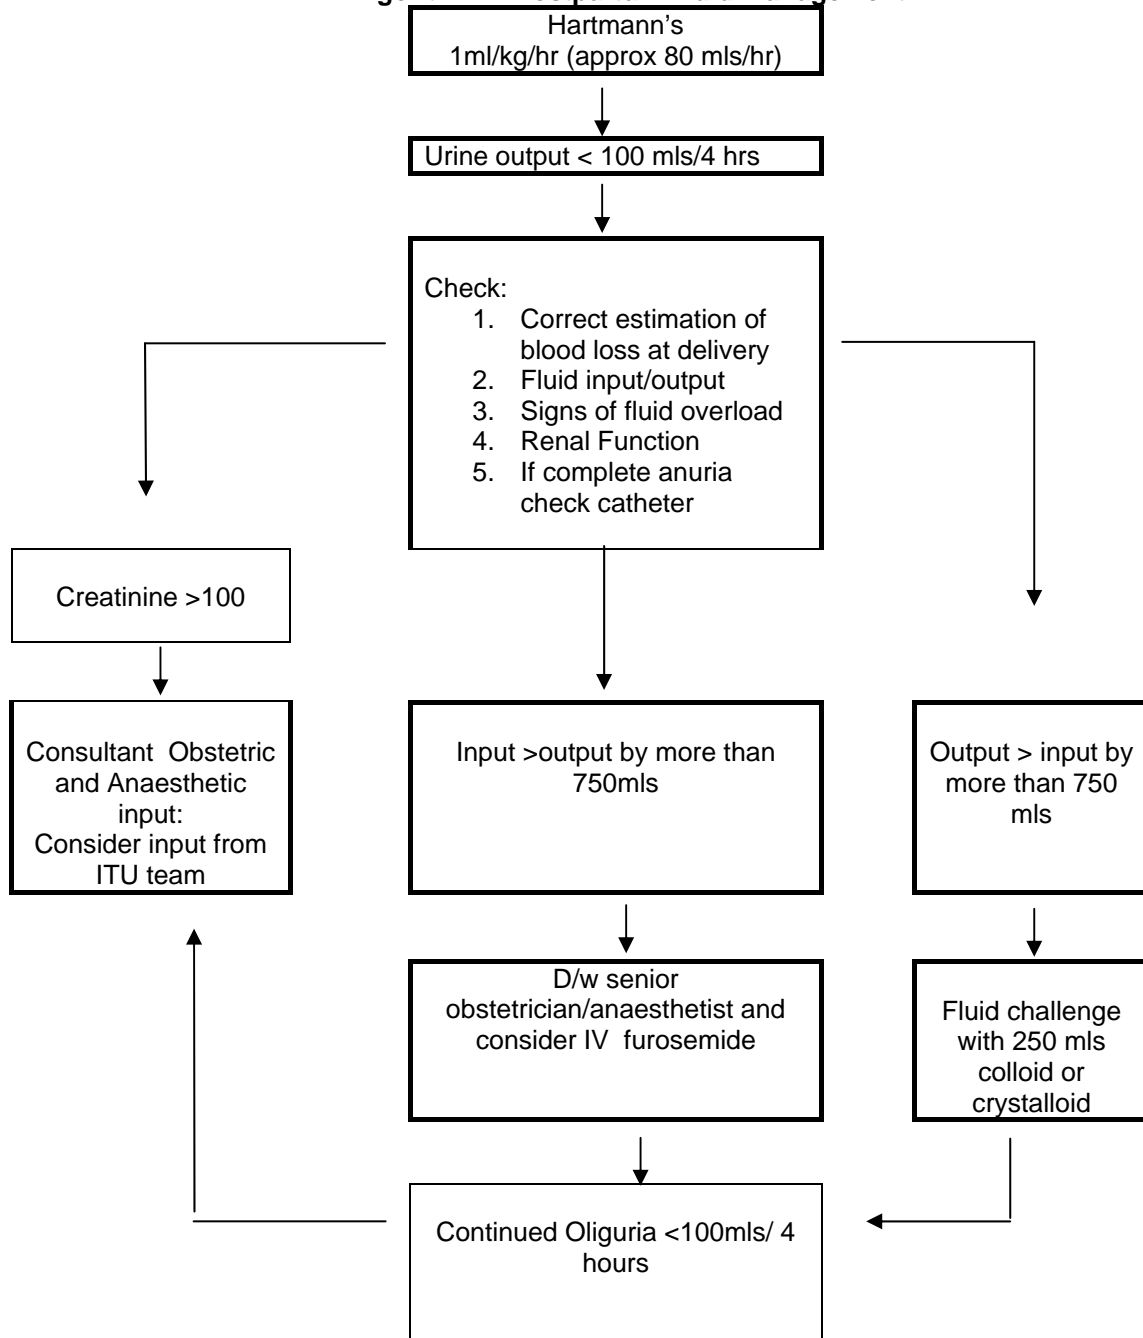

Captopril

5. The woman should be kept in until day 3-4 postnatal for the control of her blood pressure. After discharge her blood pressure should be measured every 1-2 days for two weeks until she is off medication and no longer hypertensive. A copy of the discharge letter should be faxed AND sent to the GP, as well as giving a copy to the woman and a copy being placed in the clinical records **(See appendix A)**
6. The blood pressure medication should be reduced when the BP is 130-140/80-90
7. The woman should be seen at 6-8 weeks postnatal. She may be seen in the Obstetric Medicine Clinic. Her blood pressure and urine dipstick should be checked. If she is still on medication or has more than 2+ protein on urine dipstick, her renal function should be further assessed and referral to specialist services should be considered.

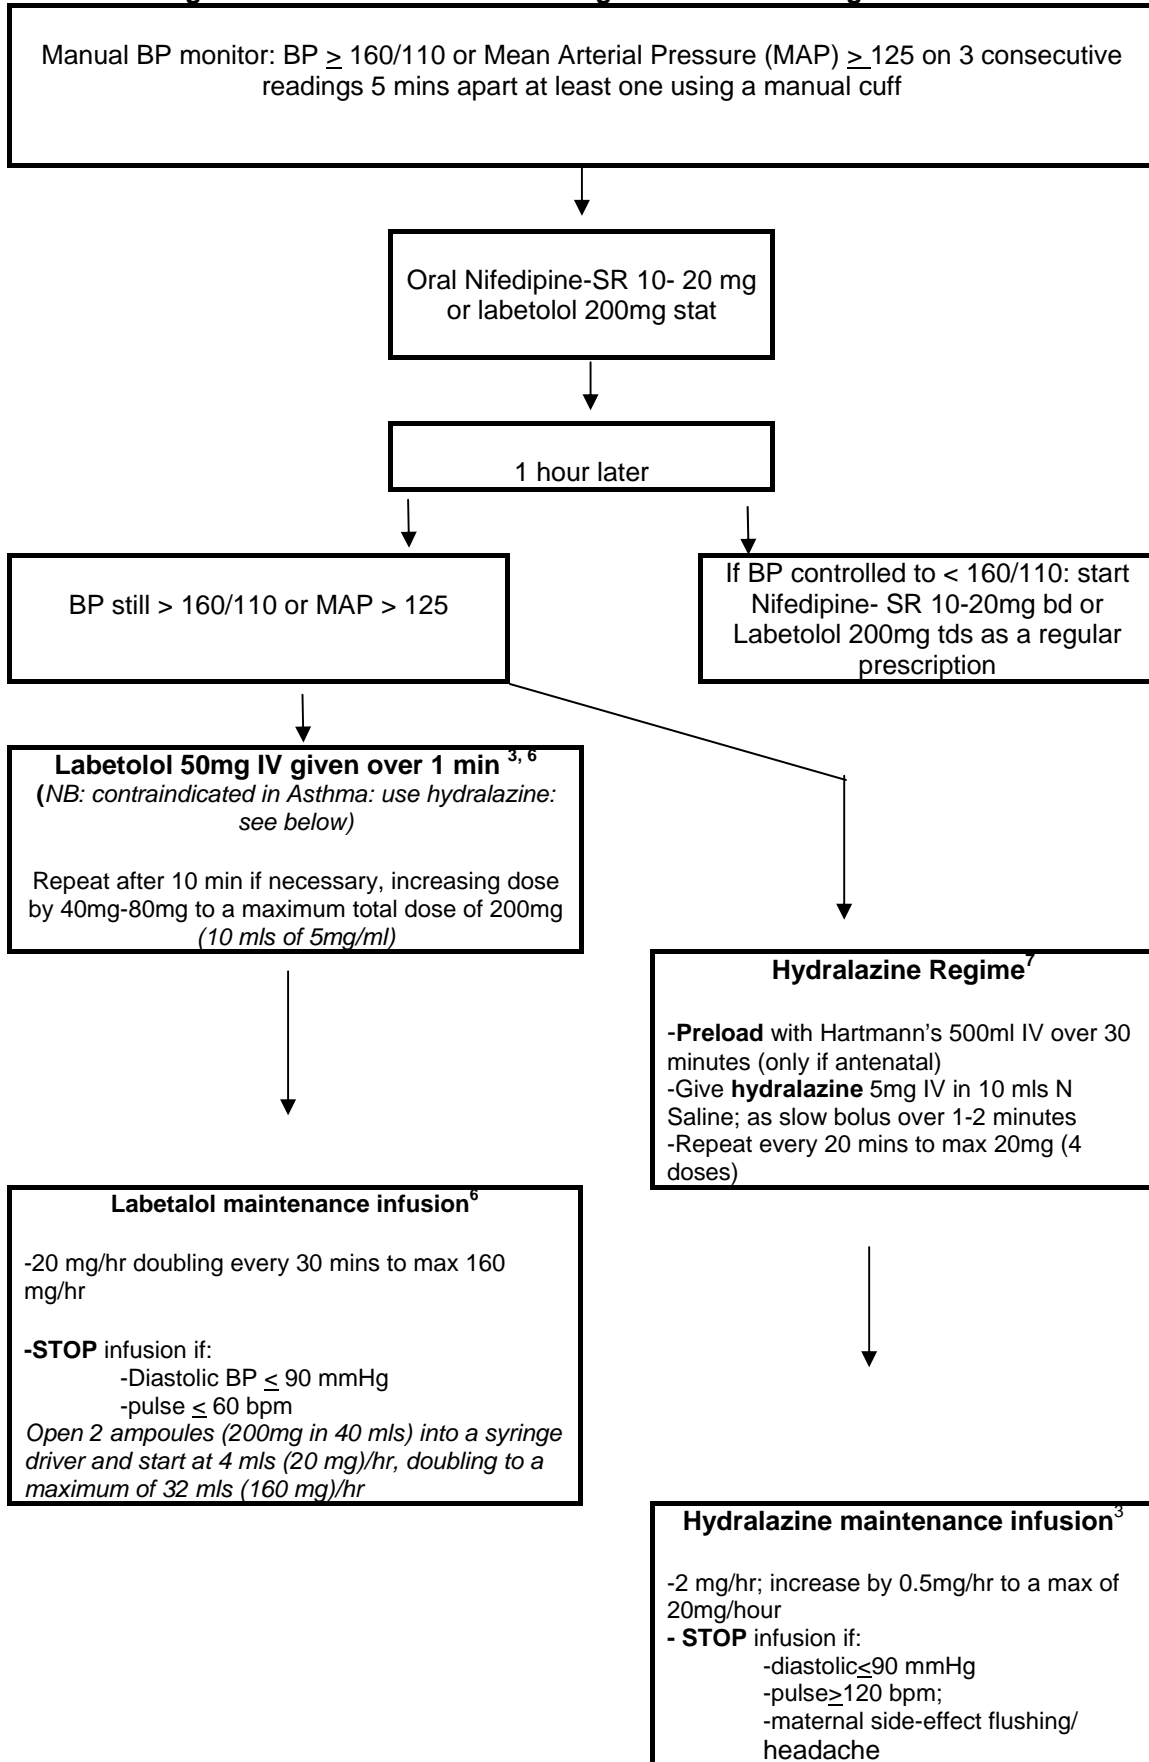

Overall management plan (Algorithm 1)

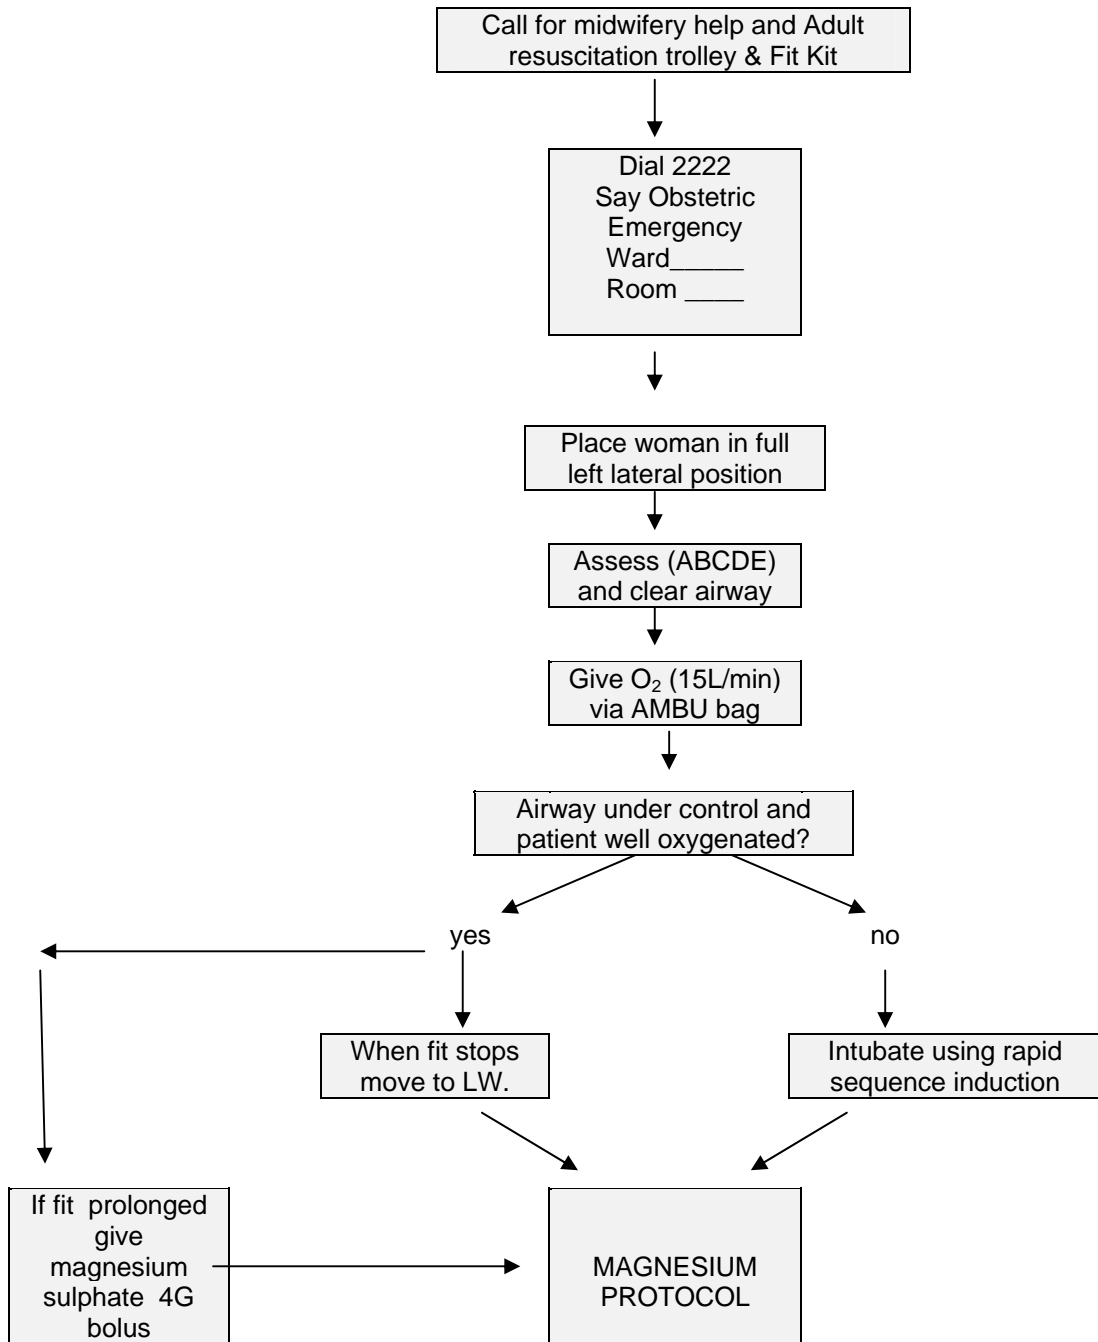

Algorithm 2: Postpartum Fluid management

Algorithm 3: Blood Pressure Management Aim for target BP 150/80-100****

Eclampsia management (Algorithm 4)

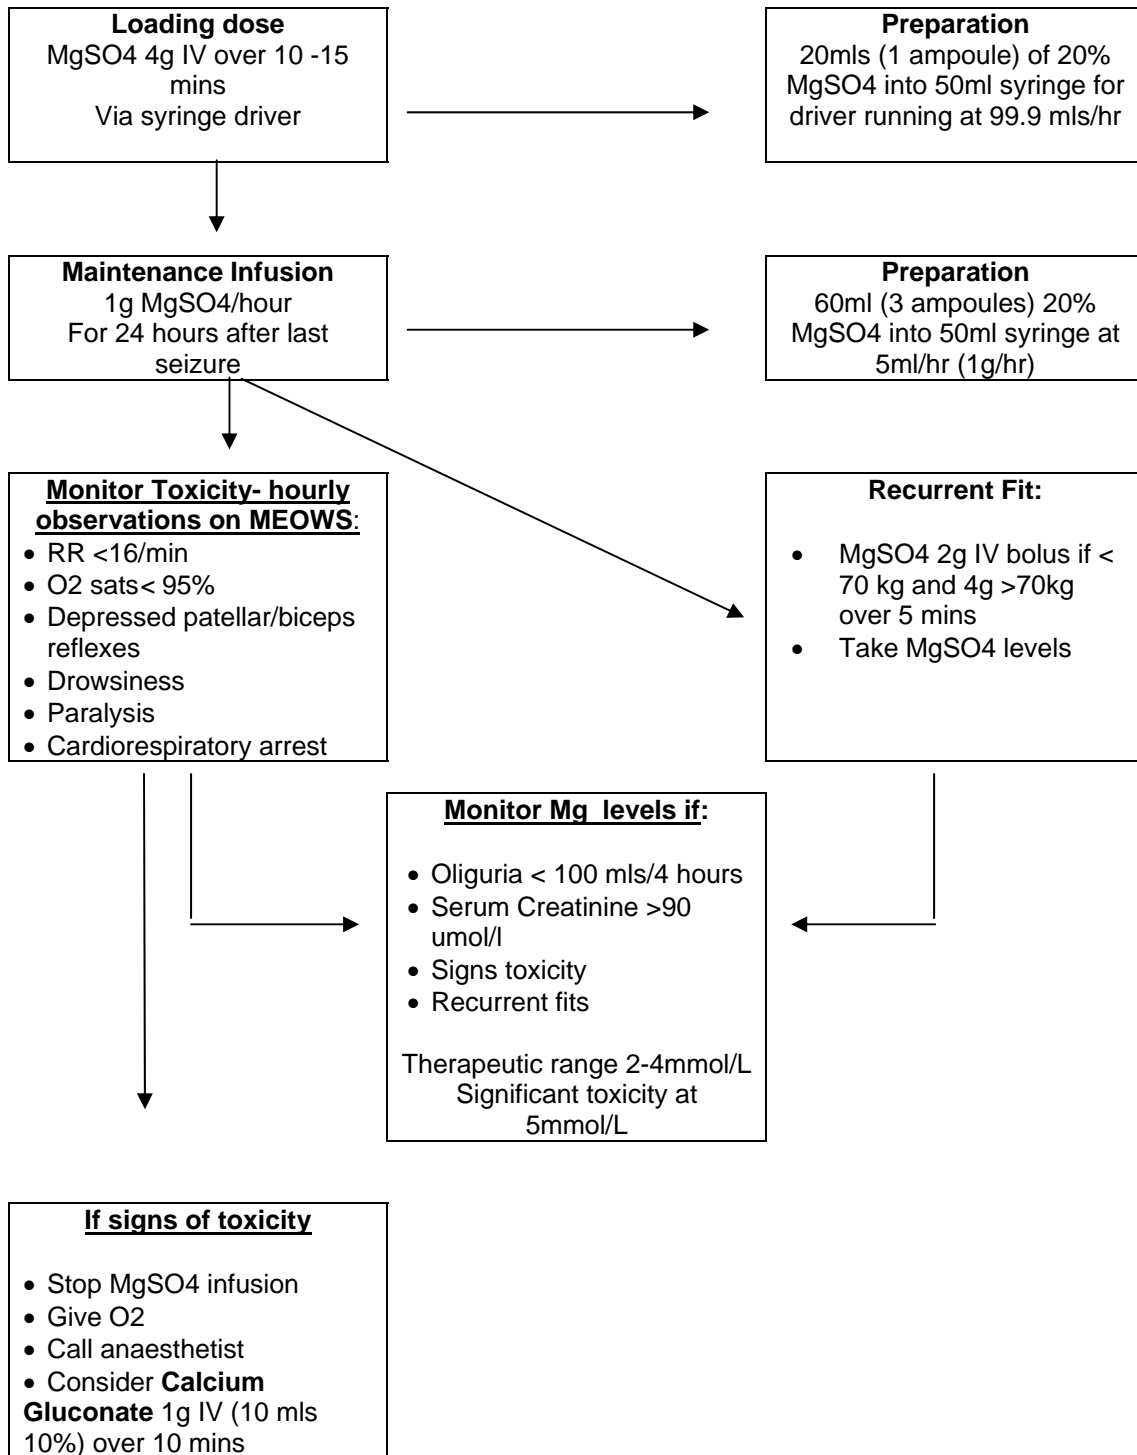

Recurrent seizures: Give further bolus of 2-4G Magnesium Sulphate (depending on weight; see algorithm 5).

Consider anaesthesia and intubation/ventilation.

A CT scan of the head must be performed in women with recurrent seizures to exclude other CNS pathology.

Algorithm 5: Magnesium Sulphate Management

| Date: | Re: Your Patient: |
| To: Dr | Name |
| | DOB |
| | Hosp No |
| | Address |
| Fax No | |
| | |

Your patient was delivered at the Whittington Hospital on.....

*****Her antenatal/postnatal course has been complicated by hypertension*****

She was discharged from Whittington on (date).....

Her Blood Pressure at booking was.....

Her Blood pressure on discharge was.....

Her Blood pressure medication on discharge was.....

*****Please send her urgently to Labour Ward (0207 288 5502) if she has any NEW symptoms suggestive of poorly controlled hypertension, pre-eclampsia or impending eclampsia*****

Her 6/52 postnatal appointment is on.....in the ANC with.....

Please see her (tick as applicable):

- In.....days time to check her blood pressure and then alternate days for up to 2 weeks.
- With a view to tailing off /stopping her medication if her BP is consistently less than 130-140/ 80-90
- Please refer her if you have any concerns about control of her hypertension.
- Any other comments.....
-
-

Yours Sincerely,

Name:

Bleep

Consultant team:

Appendix B: Audit Tool

Women's Health Maternity Audit Tool for Guideline

Severe hypertension, preeclampsia and eclampsia

Objectives of the audit:

The objective of this audit is to demonstrate compliance of the guideline in all cases of severe hypertension and severe pre-eclampsia against the following standards:

1. Severe hypertension was correctly assessed and diagnosed according to the inclusion criteria in 100% cases.
2. There were clear lines of communication between the consultant obstetrician, consultant anaesthetist, Labour Ward co-ordinator and (neonatologist if the patient was antenatal) in 100% cases.
3. There was appropriate control of blood pressure in 100% cases.
4. There was appropriate fluid management in 100% cases.
5. Magnesium Sulphate was used for the prevention of seizures if appropriate in 100% cases.
6. There was appropriate control of eclamptic seizures in 100% cases.
7. The fetus was assessed and delivery planned appropriately in 100% cases.
8. Postnatal follow-up was appropriately planned in 100% cases

Data sources

The data will be collected from case notes

Re-audit

The guideline will be audited as required.

Audit tool**Hospital No:****Date delivered:**
